

The Geometry of the Moduli Space of Curves of Genus 23

GAVRIL FARKAS

1 Introduction

The problem of describing the birational geometry of the moduli space \mathcal{M}_g of complex curves of genus g has a long history. Severi already knew in 1915 that \mathcal{M}_g is unirational for $g \leq 10$ (cf. [Sev]; see also [AC1] for a modern proof). In the same paper Severi conjectured that \mathcal{M}_g is unirational for all genera g . Then for a long period this problem seemed intractable (Mumford writes in [Mu], p.51: “Whether more \mathcal{M}_g ’s, $g \geq 11$, are unirational or not is a very interesting problem, but one which looks very hard too, especially if g is quite large”). The breakthrough came in the eighties when Eisenbud, Harris and Mumford proved that \mathcal{M}_g is of general type as soon as $g \geq 24$ and that the Kodaira dimension of \mathcal{M}_{23} is ≥ 1 (see [HM], [EH3]). We note that \mathcal{M}_g is rational for $g \leq 6$ (see [Dol] for problems concerning the rationality of various moduli spaces).

Severi’s proof of the unirationality of \mathcal{M}_g for small g was based on representing a general curve of genus g as a plane curve of degree d with δ nodes; this is possible when $d \geq 2g/3 + 2$. When the number of nodes is small, i.e. $\delta \leq (d+1)(d+2)/6$, the dominant map from the variety of plane curves of degree d and genus g to \mathcal{M}_g yields a rational parametrization of the moduli space. The two conditions involving d and δ can be satisfied only when $g \leq 10$, so Severi’s argument cannot be extended for other genera. However, using much more subtle ideas, Chang, Ran and Sernesi proved the unirationality of \mathcal{M}_g for $g = 11, 12, 13$ (see [CR1], [Se1]), while for $g = 15, 16$ they proved that the Kodaira dimension is $-\infty$ (see [CR2,4]). The remaining cases $g = 14$ and $17 \leq g \leq 23$ are still quite mysterious. Harris and Morrison conjectured in [HMo] that \mathcal{M}_g is uniruled precisely when $g < 23$.

All these facts indicate that \mathcal{M}_{23} is a very interesting transition case. Our main result is the following:

Theorem 1 *The Kodaira dimension of the moduli space of curves of genus 23 is ≥ 2 .*

We will also present some evidence for the hypothesis that the Kodaira dimension of \mathcal{M}_{23} is actually equal to 2.

Acknowledgments: I am grateful to my advisor Gerard van der Geer, for proposing the problem and for continuous support and guidance. I thank Joe Harris for many inspiring discussions during my stay at Harvard. I also benefited from conversations with Marc Coppens and Carel Faber.

2 Multicanonical linear systems and the Kodaira dimension of \mathcal{M}_g

We study three multicanonical divisors on \mathcal{M}_{23} , which are (modulo some boundary components) of Brill-Noether type, and we conclude by looking at their relative position that $\kappa(\mathcal{M}_{23}) \geq 2$.

We review some notations. We shall denote by $\overline{\mathcal{M}}_g$ and $\overline{\mathcal{C}}_g$ the moduli spaces of stable and 1-pointed stable curves of genus g over \mathbb{C} . If C is a smooth algebraic curve of genus g , we consider for any r and d , the scheme whose points are the \mathfrak{g}_d^r 's on C , that is,

$$G_d^r(C) = \{(\mathcal{L}, V) : \mathcal{L} \in \text{Pic}^d(C), V \subseteq H^0(C, \mathcal{L}), \dim(V) = r + 1\},$$

(cf. [ACGH]) and denote the associated Brill-Noether locus in \mathcal{M}_g by

$$\mathcal{M}_{g,d}^r := \{[C] \in \mathcal{M}_g : G_d^r(C) \neq \emptyset\},$$

and by $\overline{\mathcal{M}}_{g,d}^r$ its closure in $\overline{\mathcal{M}}_g$.

The distribution of linear series on algebraic curves is governed (to some extent) by the *Brill-Noether number*

$$\rho(g, r, d) := g - (r + 1)(g - d + r).$$

The Brill-Noether Theorem asserts that when $\rho(g, r, d) \geq 0$ every curve of genus g possesses a \mathfrak{g}_d^r , while when $\rho(g, r, d) < 0$ the general curve of genus g has no \mathfrak{g}_d^r 's, hence in this case the Brill-Noether loci are proper subvarieties of \mathcal{M}_g . When $\rho(g, r, d) < 0$, the naive expectation that $-\rho(g, r, d)$ is the codimension of $\mathcal{M}_{g,d}^r$ inside \mathcal{M}_g , is in general way off the mark, since there are plenty of examples of Brill-Noether loci of unexpected dimension (cf. [EH2]). However, we have Steffen's result in one direction (see [St]):

If $\rho(g, r, d) < 0$ then each component of $\mathcal{M}_{g,d}^r$ has codimension at most $-\rho(g, r, d)$ in \mathcal{M}_g .

On the other hand, when the Brill-Noether number is not very negative, the Brill-Noether loci tend to behave nicely. Existence of components of $\mathcal{M}_{g,d}^r$ of the expected dimension has been proved for a rather wide range, namely for those g, r, d such that $\rho(g, r, d) < 0$, and

$$\rho(g, r, d) \geq \begin{cases} -g + r + 3 & \text{if } r \text{ is odd;} \\ -rg/(r + 2) + r + 3 & \text{if } r \text{ is even.} \end{cases}$$

We have a complete answer only when $\rho(g, r, d) = -1$. Eisenbud and Harris have proved in [EH2] that in this case $\mathcal{M}_{g,d}^r$ has a unique divisorial component, and using the previously mentioned theorem of Steffen's, we obtain the following result:

If $\rho(g, r, d) = -1$, then $\overline{\mathcal{M}}_{g,d}^r$ is an irreducible divisor of $\overline{\mathcal{M}}_g$.

We will also need Edidin's result (see [Ed2]) which says that for $g \geq 12$ and $\rho(g, r, d) = -2$, all components of $\mathcal{M}_{g,d}^r$ have codimension 2. We can get codimension 1 Brill-Noether conditions only for the genera g for which $g + 1$ is composite. In that case we can write

$$g + 1 = (r + 1)(s - 1), \quad s \geq 3$$

and set $d := rs - 1$. Obviously $\rho(g, r, d) = -1$ and $\overline{\mathcal{M}}_{g,d}^r$ is an irreducible divisor. Furthermore, its class has been computed (cf. [EH3]):

$$[\overline{\mathcal{M}}_{g,d}^r] = c_{g,r,d} \left((g+3)\lambda - \frac{g+1}{6}\delta_0 - \sum_{i=1}^{[g/2]} i(g-i)\delta_i \right),$$

where $c_{g,r,d}$ is a positive rational number equal to $3\mu/(2g-4)$, with μ being the number of \mathfrak{g}_d^r 's on a general pointed curve (C_0, q) of genus $g-2$ with ramification sequence $(0, 1, 2, \dots, 2)$ at q . For $g = 23$ we have the following possibilities:

$$(r, s, d) = (1, 13, 12), (11, 3, 32), (2, 9, 17), (7, 4, 24), (3, 7, 20), (5, 5, 24).$$

It is immediate by Serre duality, that cases $(1, 13, 12)$ and $(11, 3, 32)$ yield the same divisor on \mathcal{M}_{23} , namely the 12-gonal locus \mathcal{M}_{12}^1 ; similarly, cases $(2, 9, 17)$ and $(7, 4, 24)$ yield the divisor \mathcal{M}_{17}^2 of curves having a \mathfrak{g}_{17}^2 , while cases $(3, 7, 20)$ and $(5, 5, 24)$ give rise to \mathcal{M}_{20}^3 , the divisor of curves having a \mathfrak{g}_{20}^3 . Note that when the genus we are referring to is clear from the context, we write $\mathcal{M}_d^r = \mathcal{M}_{g,d}^r$.

By comparing the classes of the Brill-Noether divisors to the class of the canonical divisor $K_{\overline{\mathcal{M}}_{g,reg}} = 13\lambda - 2\delta_0 - 3\delta_1 - \dots - 2\delta_{[g/2]}$, at least in the case when $g+1$ is composite we can infer that

$$K_{\overline{\mathcal{M}}_{g,reg}} = a[\overline{\mathcal{M}}_{g,d}^r] + b\lambda + (\text{positive combination of } \delta_0, \dots, \delta_{[g/2]}),$$

where a is a positive rational number, while $b > 0$ as long as $g \geq 24$ but $b = 0$ for $g = 23$. As it is well-known that λ is big on $\overline{\mathcal{M}}_g$, it follows that \mathcal{M}_g is of general type for $g \geq 24$ and that it has non-negative Kodaira dimension when $g = 23$. Specifically for $g = 23$, we get that there are positive integer constants m, m_1, m_2, m_3 such that:

$$mK = m_1[\overline{\mathcal{M}}_{12}^1] + E, \quad mK = m_2[\overline{\mathcal{M}}_{17}^2] + E, \quad mK = m_3[\overline{\mathcal{M}}_{20}^3] + E, \quad (1)$$

where E is the same positive combination of $\delta_1, \dots, \delta_{11}$.

Proposition 2.1 (Eisenbud-Harris, [EH3]) *There exists a smooth curve of genus 23 that possesses a \mathfrak{g}_{12}^1 , but no \mathfrak{g}_{17}^2 . It follows that $\kappa(\mathcal{M}_{23}) \geq 1$.*

Harris and Mumford proved (cf. [HM]) that $\overline{\mathcal{M}}_g$ has only canonical singularities for $g \geq 4$, hence $H^0(\overline{\mathcal{M}}_{g,reg}, nK) = H^0(\widetilde{\mathcal{M}}_g, nK)$ for each $n \geq 0$, with $\widetilde{\mathcal{M}}_g$ a desingularization of $\overline{\mathcal{M}}_g$. We already know that $\dim(\text{Im}\phi_{mK}) \geq 1$, where $\phi_{mK} : \overline{\mathcal{M}}_{23} \dashrightarrow \mathbb{P}^\nu$ is the multicanonical map, m being as in (1). We will prove that $\kappa(\mathcal{M}_{23}) \geq 2$. Indeed, let us assume that $\dim(\text{Im}\phi_{mK}) = 1$. Denote by $C := \overline{\text{Im}\phi_{mK}}$ the Kodaira image of $\overline{\mathcal{M}}_{23}$. We reach a contradiction by proving two things:

- α) The Brill-Noether divisors $\mathcal{M}_{12}^1, \mathcal{M}_{17}^2$ and \mathcal{M}_{20}^3 are mutually distinct.
- β) There exist smooth curves of genus 23 which belong to exactly two of the Brill-Noether divisors from above.

This suffices in order to prove Theorem 1: since $\overline{\mathcal{M}}_{12}^1, \overline{\mathcal{M}}_{17}^2$ and $\overline{\mathcal{M}}_{20}^3$ are part of different

multicanonical divisors, they must be contained in different fibres of the multicanonical map ϕ_{mK} . Hence there exists different points $x, y, z \in C$ such that

$$\mathcal{M}_{12}^1 = \overline{\phi^{-1}(x)} \cap \mathcal{M}_{23}, \quad \mathcal{M}_{17}^2 = \overline{\phi^{-1}(y)} \cap \mathcal{M}_{23}, \quad \mathcal{M}_{20}^3 = \overline{\phi^{-1}(z)} \cap \mathcal{M}_{23}.$$

It follows that the set-theoretic intersection of any two of them will be contained in the base locus of $|mK_{\overline{\mathcal{M}_{23}}}|$. In particular:

$$\text{supp}(\mathcal{M}_{12}^1) \cap \text{supp}(\mathcal{M}_{17}^2) = \text{supp}(\mathcal{M}_{17}^2) \cap \text{supp}(\mathcal{M}_{20}^3) = \text{supp}(\mathcal{M}_{20}^3) \cap \text{supp}(\mathcal{M}_{12}^1), \quad (2)$$

and this contradicts β). We complete the proof of α) and β) is Section 5.

3 Deformation theory for \mathfrak{g}_d^r 's and limit linear series

We recall a few things about the variety parametrising \mathfrak{g}_d^r 's on the fibres of the universal curve (cf. [AC2]), and then we recap on the theory of limit linear series (cf. [EH1], [Mod]), which is our main technique for the study of \mathcal{M}_{23} .

Given g, r, d and a point $[C] \in \mathcal{M}_g$, there is a connected neighbourhood U of $[C]$, a finite ramified covering $h : \mathcal{M} \rightarrow U$, such that \mathcal{M} is a fine moduli space of curves (i.e. there exists $\xi : \mathcal{C} \rightarrow \mathcal{M}$ a universal curve), and a proper variety over \mathcal{M} ,

$$\pi : \mathcal{G}_d^r \rightarrow \mathcal{M}$$

which parametrizes classes of couples (C, l) , with $[C] \in \mathcal{M}$ and $l \in G_d^r(C)$, where we have made the identification $C = \xi^{-1}([C])$.

Let (C, l) be a point of \mathcal{G}_d^r corresponding to a curve C and a linear series $l = (\mathcal{L}, V)$, where $\mathcal{L} \in \text{Pic}^d(C)$, $V \subseteq H^0(C, \mathcal{L})$, and $\dim(V) = r + 1$. By choosing a basis in V , one has a morphism $f : C \rightarrow \mathbb{P}^r$. The normal sheaf of f is defined through the exact sequence

$$0 \longrightarrow T_C \longrightarrow f^*(T_{\mathbb{P}^r}) \longrightarrow N_f \longrightarrow 0. \quad (3)$$

By dividing out the torsion of N_f one gets to the exact sequence

$$0 \longrightarrow \mathcal{K}_f \longrightarrow N_f \longrightarrow N'_f \longrightarrow 0, \quad (4)$$

where the torsion sheaf \mathcal{K}_f (the cuspidal sheaf) is based at those points $x \in C$ where $df(x) = 0$, and N'_f is locally free of rank $r - 1$. The tangent space $T_{(C, l)}(\mathcal{G}_d^r)$ fits into an exact sequence (cf. [AC2]):

$$0 \longrightarrow \mathbb{C} \longrightarrow \text{Hom}(V, V) \longrightarrow H^0(C, N_f) \longrightarrow T_{(C, l)}(\mathcal{G}_d^r) \longrightarrow 0, \quad (5)$$

from which we have that $\dim T_{(C, l)}(\mathcal{G}_d^r) = 3g - 3 + \rho(g, r, d) + h^1(C, N_f)$.

Proposition 3.1 *Let C be a curve and $l \in G_d^r(C)$ a base point free linear series. Then the variety \mathcal{G}_d^r is smooth and of dimension $3g - 3 + \rho(g, r, d)$ at the point (C, l) if and only if $H^1(C, N_f) = 0$.*

Remark: The condition $H^1(C, N_f) = 0$ is automatically satisfied for $r = 1$ as N_f is a sheaf with finite support. Thus \mathcal{G}_d^1 is smooth of dimension $2g + 2d - 5$. It follows that \mathcal{G}_d^1 is birationally equivalent to the d -gonal locus \mathcal{M}_d^1 when $d < (g + 2)/2$.

Limit linear series try to answer questions of the following kind: what happens to a family of \mathfrak{g}_d^r 's when a smooth curve specializes to a reducible curve? Limit linear series solve such problems for a class of reducible curves, those of compact type. A curve C is of *compact type* if the dual graph is a tree. A curve C is *tree-like* if, after deleting edges leading from a node to itself, the dual graph becomes a tree.

Let C be a smooth curve of genus g and $l = (\mathcal{L}, V) \in G_d^r(C)$, $\mathcal{L} \in \text{Pic}^d(C)$, $V \subseteq H^0(C, \mathcal{L})$, and $\dim(V) = r + 1$. Fix $p \in C$ a point. By ordering the finite set $\{\text{ord}_p(\sigma)\}_{\sigma \in V}$ one gets the *vanishing sequence* of l at p :

$$a^l(p) : 0 \leq a_0^l(p) < \dots < a_r^l(p) \leq d.$$

The *ramification sequence* of l at p

$$\alpha^l(p) : 0 \leq \alpha_0^l(p) \leq \dots \leq \alpha_r^l(p) \leq d - r$$

is defined as $\alpha_i^l(p) = a_i^l(p) - i$ and the *weight* of l at p is

$$w^l(p) = \sum_{i=0}^r \alpha_i^l(p).$$

A *Schubert index* of type (r, d) is a sequence of integers $\beta : 0 \leq \beta_0 \leq \dots \beta_r \leq d - r$. If α and β are Schubert indices of type (r, d) we write $\alpha \leq \beta \iff \alpha_i \leq \beta_i, i = 0, \dots, r$. The point p is said to be a *ramification point* of l if $w^l(p) > 0$. The linear series l is said to have a *cusp* at p if $\alpha^l(p) \geq (0, 1, \dots, 1)$. For C a tree-like curve, $p_1, \dots, p_n \in C$ smooth points and $\alpha^1, \dots, \alpha^n$ Schubert indices of type (r, d) , we define

$$G_d^r(C, (p_1, \alpha^1), \dots, (p_n, \alpha^n)) := \{l \in G_d^r(C) : \alpha^l(p_1) \geq \alpha^1, \dots, \alpha^l(p_n) \geq \alpha^n\}.$$

This scheme can be realized naturally as a determinantal variety and its expected dimension is

$$\rho(g, r, d, \alpha^1, \dots, \alpha^n) := \rho(g, r, d) - \sum_{i=1}^n \sum_{j=0}^r \alpha_j^i.$$

If C is a curve of compact type, a *crude limit* \mathfrak{g}_d^r on C is a collection of ordinary linear series $l = \{l_Y \in G_d^r(Y) : Y \subseteq C \text{ is a component}\}$, satisfying the following compatibility condition: if Y and Z are components of C , with $\{p\} = Y \cap Z$, then

$$a_i^{l_Y}(p) + a_{r-i}^{l_Z}(p) \geq d, \text{ for } i = 0, \dots, r.$$

If equality holds everywhere, we say that l is a *refined limit* \mathfrak{g}_d^r . The ‘honest’ linear series $l_Y \in G_d^r(Y)$ is called the Y -aspect of the limit linear series l .

We will often use the additivity of the Brill-Noether number: if C is a curve of compact

type, for each component $Y \subseteq C$, let q_1, \dots, q_s be the points where Y meets the other components of C . Then for any limit \mathbf{g}_d^r on C we have the following inequality:

$$\rho(g, r, d) \geq \sum_{Y \subseteq C} \rho(l_Y, \alpha^{l_Y}(q_1), \dots, \alpha^{l_Y}(q_s)), \quad (6)$$

with equality if and only if l is a refined limit linear series.

It has been proved in [EH1] that limit linear series arise indeed as limits of ordinary linear series on smooth curves. Suppose we are given a family $\pi : \mathcal{C} \rightarrow B$ of genus g curves, where $B = \text{Spec}(R)$ with R a complete discrete valuation ring. Assume furthermore that \mathcal{C} is a smooth surface and that if $0, \eta$ denote the special and generic point of B respectively, the central fibre C_0 is reduced and of compact type, while the generic geometric fibre C_η is smooth and irreducible. If $l_\eta = (\mathcal{L}_\eta, V_\eta)$ is a \mathbf{g}_d^r on X_η , there is a canonical way to associate a crude limit series l_0 on C_0 which is the limit of l_η in a natural way: for each component Y of C_0 , there exists a unique line bundle \mathcal{L}^Y on \mathcal{C} such that

$$\mathcal{L}_{|\mathcal{C}_\eta}^Y = \mathcal{L}_\eta \text{ and } \deg_Z(\mathcal{L}_{|Z}^Y) = 0,$$

for any component Z of C_0 with $Z \neq Y$. (This implies of course that $\deg_Y(\mathcal{L}_{|Y}^Y) = d$). Define $V^Y = V_\eta \cap H^0(\mathcal{C}, \mathcal{L}^Y) \subseteq H^0(\mathcal{C}_\eta, \mathcal{L}_\eta)$. Clearly, V^Y is a free R -module of rank $r + 1$. Moreover, the composite homomorphism

$$V^Y(0) \rightarrow (\pi_* \mathcal{L}^Y)(0) \rightarrow H^0(C_0, \mathcal{L}_{|C_0}^Y) \rightarrow H^0(Y, \mathcal{L}_{|Y}^Y)$$

is injective, hence $l_Y = (\mathcal{L}_{|Y}^Y, V^Y(0))$ is an ordinary \mathbf{g}_d^r on Y . One proves that $l = \{l_Y : Y \text{ component of } C_0\}$ is a limit linear series.

If C is a reducible curve of compact type, l a limit \mathbf{g}_d^r on C , we say that l is *smoothable* if there exists $\pi : \mathcal{C} \rightarrow B$ a family of curves with central fibre $C = C_0$ as above, and $(\mathcal{L}_\eta, V_\eta)$ a \mathbf{g}_d^r on the generic fibre C_η whose limit on C (in the sense previously described) is l .

Remark: If a stable curve of compact type C , has no limit \mathbf{g}_d^r 's, then $[C] \notin \overline{\mathcal{M}}_{g,d}^r$. If there exists a smoothable limit \mathbf{g}_d^r on C , then $[C] \in \overline{\mathcal{M}}_{g,d}^r$.

Now we explain a criterion due to Eisenbud and Harris (cf. [EH1]), which gives a sufficient condition for a limit \mathbf{g}_d^r to be smoothable. Let l be a limit \mathbf{g}_d^r on a curve C of compact type. Fix $Y \subseteq C$ a component, and $\{q_1, \dots, q_s\} = Y \cap \overline{(C - Y)}$. Let

$$\pi : \mathcal{Y} \rightarrow B, \quad \tilde{q}_i : B \rightarrow \mathcal{Y}$$

be the versal deformation space of (Y, q_1, \dots, q_s) . The base B can be viewed as a small $(3g(Y) - 3 + s)$ -dimensional polydisk. Using general theory one constructs a proper scheme over B ,

$$\sigma : \mathcal{G}_d^r(\mathcal{Y}/B; (\tilde{q}_i, \alpha^{l_Y}(q_i))_{i=1}^s) \rightarrow B$$

whose fibre over each $b \in B$ is $\sigma^{-1}(b) = G_d^r(Y_b, (\tilde{q}_i(b), \alpha^{l_Y}(q_i))_{i=1}^s)$. One says that l is *dimensionally proper with respect to Y* , if the Y -aspect l_Y is contained in some component \mathcal{G} of $\mathcal{G}_d^r(\mathcal{Y}/B; (\tilde{q}_i, \alpha^{l_Y}(q_i))_{i=1}^s)$ of the expected dimension, i.e.

$$\dim \mathcal{G} = \dim B + \rho(l_Y, \alpha^{l_Y}(q_1), \dots, \alpha^{l_Y}(q_s)).$$

One says that l is *dimensionally proper*, if it is dimensionally proper with respect to any component $Y \subseteq C$. The ‘Regeneration Theorem’ (cf. [EH1]) states that every dimensionally proper limit linear series is smoothable.

The next result is a ‘strong Brill-Noether Theorem’, i.e. it not only asserts a Brill-Noether type statement, but also singles out the locus where the statement fails.

Proposition 3.2 (Eisenbud-Harris) *Let C be a tree-like curve and for any component $Y \subseteq C$, denote by $q_1, \dots, q_s \in Y$ the points where Y meets the other components of C . Assume that for each Y the following conditions are satisfied:*

- a. If $g(Y) = 1$ then $s = 1$.*
- b. If $g(Y) = 2$ then $s = 1$ and q is not a Weierstrass point.*
- c. If $g(Y) \geq 3$ then (Y, q_1, \dots, q_s) is a general s -pointed curve.*

Then for $p_1, \dots, p_t \in C$ general points, $\rho(l, \alpha^l(p_1), \dots, \alpha^l(p_t)) \geq 0$ for any limit linear series on C .

Simple examples involving pointed elliptic curves show that the condition $\rho(g, r, d) \geq \sum_{i=1}^t w^l(p_i)$ does not guarantee the existence of a linear series $l \in G_d^r(C)$ with prescribed ramification at general points $p_1, p_2, \dots, p_t \in C$. The appropriate condition in the pointed case can be given in terms of Schubert cycles. Let $\alpha = (\alpha_0, \dots, \alpha_r)$ be a Schubert index of type (r, d) and

$$\mathbb{C}^{d+1} = W_0 \supset W_1 \supset \dots \supset W_{d+1} = 0$$

a decreasing flag of linear subspaces. We consider the Schubert cycle in the Grassmanian,

$$\sigma_\alpha = \{\Lambda \in G(r+1, d+1) : \dim(\Lambda \cap W_{\alpha_i+i}) \geq r+1-i, i=0, \dots, r\}.$$

For a general t -pointed curve (C, p_1, \dots, p_t) of genus g , and $\alpha^1, \dots, \alpha^t$ Schubert indices of type (r, d) , the necessary and sufficient condition that C has a \mathfrak{g}_d^r with ramification α^i at p_i is that

$$\sigma_{\alpha^1} \cdot \dots \cdot \sigma_{\alpha^t} \cdot \sigma_{(0,1,\dots,1)}^g \neq 0 \text{ in } H^*(G(r+1, d+1), \mathbb{Z}). \quad (7)$$

In the case $t = 1$ this condition can be made more explicit (cf. [EH3]): a general pointed curve (C, p) of genus g carries a \mathfrak{g}_d^r with ramification sequence $(\alpha_0, \dots, \alpha_r)$ at p , if and only if

$$\sum_{i=0}^r (\alpha_i + g - d + r)_+ \leq g, \quad (8)$$

where $x_+ = \max\{x, 0\}$. One can make the following simple but useful observation:

Proposition 3.3 *Let (C, p, q) be a general 2-pointed curve of genus g and $(\alpha_0, \dots, \alpha_r)$ a Schubert index of type (r, d) . Then C has a \mathfrak{g}_d^r having ramification sequence $(\alpha_0, \dots, \alpha_r)$ at p and a cusp at q if and only if*

$$\sum_{i=0}^r (\alpha_i + g + 1 - d + r)_+ \leq g + 1.$$

Proof: The condition for the existence of the \mathfrak{g}_d^r with ramification α at p and a cusp at q is that $\sigma_\alpha \cdot \sigma_{(0,1,\dots,1)}^{g+1} \neq 0$ (cf. (7)). According to the Littlewood-Richardson rule (see [F]), this is equivalent with $\sum_{i=0}^r (\alpha_i + g + 1 - d + r)_+ \leq g + 1$. \square

4 A few consequences of limit linear series

We investigate the Brill-Noether theory of a 2-pointed elliptic curve (see also [EH4]), and we prove that $\overline{\mathcal{M}}_{g,d}^r \cap \Delta_1$ is irreducible for $\rho(g, r, d) = -1$.

Proposition 4.1 *Let (E, p, q) be a two-pointed elliptic curve. Consider the sequences*

$$a : a_0 < a_1 < \dots < a_r \leq d, \quad b : b_0 < b_1 < \dots < b_r \leq d.$$

1. *For any linear series $l = (\mathcal{L}, V) \in G_d^r(E)$ one has that $\rho(l, \alpha^l(p), \alpha^l(q)) \geq -r$. Furthermore, if $\rho(l, \alpha^l(p), \alpha^l(q)) \leq -1$, then $p - q \in \text{Pic}^0(E)$ is a torsion class.*
2. *Assume that the sequences a and b satisfy the inequalities: $d - 1 \leq a_i + b_{r-i} \leq d$, $i = 0, \dots, r$. Then there exists at most one linear series $l \in G_d^r(E)$ such that $\alpha^l(p) = a$ and $\alpha^l(q) = b$. Moreover, there exists exactly one such linear series $l = (\mathcal{O}_E(D), V)$ with $D \in E^{(d)}$, if and only if for each $i = 0, \dots, r$ the following is satisfied: if $a_i + b_{r-i} = d$, then $D \sim a_i p + b_{r-i} q$, and if $(a_i + 1) p + b_{r-i} q \sim D$, then $a_{i+1} = a_i + 1$.*

Proof: In order to prove 1. it is enough to notice that for dimensional reasons there must be sections $\sigma_i \in V$ such that $\text{div}(\sigma_i) \geq a_i^l(p) p + a_{r-i}^l(q) q$, therefore, $a_i^l(p) + a_{r-i}^l(q) \leq d$. By adding up all these inequalities, we get that $\rho(l, \alpha^l(p), \alpha^l(q)) \geq -r$. Furthermore, $\rho(l, \alpha^l(p), \alpha^l(q)) \leq -1$ precisely when for at least two values $i < j$ we have equalities $a_i + b_{r-i} = d$, $a_j + b_{r-j} = d$, which means that there are sections $\sigma_i, \sigma_j \in V$ such that $\text{div}(\sigma_i) = a_i p + b_{r-i} q$, $\text{div}(\sigma_j) = a_j p + b_{r-j} q$. By subtracting, we see that $p - q \in \text{Pic}^0(E)$ is torsion. The second part of the Proposition is in fact Prop.5.2 from [EH4]. \square

Proposition 4.2 *Let g, r, d be such that $\rho(g, r, d) = -1$. Then the intersection $\overline{\mathcal{M}}_{g,d}^r \cap \Delta_1$ is irreducible.*

Proof: Let Y be an irreducible component of $\overline{\mathcal{M}}_{g,d}^r \cap \Delta_1$. Either $Y \cap \text{Int} \Delta_1 \neq \emptyset$, hence $Y = \overline{Y \cap \text{Int} \Delta_1}$, or $Y \subseteq \Delta_1 - \text{Int} \Delta_1$. The second alternative never occurs. Indeed, if $Y \subseteq \Delta_1 - \text{Int} \Delta_1$, then since $\text{codim}(Y, \overline{\mathcal{M}}_g) = 2$, Y must be one of the irreducible components of $\Delta_1 - \text{Int} \Delta_1$. The components of $\Delta_1 - \text{Int} \Delta_1$ correspond to curves with two nodes. We list these components (see [Ed1]):

- For $1 \leq j \leq g - 2$, Δ_{1j} is the closure of the locus in $\overline{\mathcal{M}}_g$ whose general point corresponds to a chain composed of an elliptic curve, a curve of genus $g - j - 1$, and a curve of genus j .
- The component Δ_{01} , whose general point corresponds to the union of a smooth elliptic curve and an irreducible nodal curve of genus $g - 2$.
- The component $\Delta_{0,g-1}$ whose general point corresponds to the union of a smooth curve of genus $g - 1$ and an irreducible rational curve.

As the general point of $\Delta_{1,j}$, $\Delta_{0,1}$ or $\Delta_{0,g-1}$ is a tree-like curve which satisfies the conditions of Prop.3.2 it follows that such a curve satisfies the ‘strong’ Brill-Noether Theorem, hence $\Delta_{1,j} \not\subseteq \overline{\mathcal{M}}_{g,d}^r$, $\Delta_{0,1} \not\subseteq \overline{\mathcal{M}}_{g,d}^r$ and $\Delta_{0,g-1} \not\subseteq \overline{\mathcal{M}}_{g,d}^r$, a contradiction. So, we are left with the first possibility: $Y = \overline{Y \cap \text{Int}\Delta_1}$. We are going to determine the general point $[C] \in Y \cap \text{Int}\Delta_1$. Let $X = C \cup E$, $g(C) = g - 1$, E elliptic, $E \cap C = \{p\}$ such that X carries a limit \mathfrak{g}_d^r , say l . By the additivity of the Brill-Noether number, we have:

$$-1 = \rho(g, r, d) \geq \rho(l, C, p) + \rho(l, E, p).$$

Since $\rho(l, E, p) \geq 0$, it follows that $\rho(l, C, p) \leq -1$, so $w^{l_C}(p) \geq r$. Let us denote by

$$\beta : \mathcal{C}_{g-1} \times \mathcal{C}_1 \rightarrow \text{Int}\Delta_1$$

the natural map given by $\beta([C, p], [E, q]) = [X := C \cup E/p \sim q]$. We claim that if we choose X generically, then $\alpha_0^{l_C}(p) = 0$. If not, p is a base point of l_C and after removing the base point we get that $[C] \in \mathcal{M}_{g-1,d-1}^r$. Note that $\rho(g-1, r, d-1) = -2$, so $\dim \mathcal{M}_{g-1,d-1}^r = 3g-8$ (cf. [Ed2]). If we denote by $\pi : \mathcal{C}_{g-1} \rightarrow \mathcal{M}_{g-1}$ the morphism which ‘forgets the point’, we get that

$$\dim \beta(\pi^{-1}(\mathcal{M}_{g-1,d-1}^r) \times \mathcal{C}_1) = 3g-6 < \dim Y,$$

a contradiction. Hence, for the generic $[X] \in Y$ we must have $\alpha_0^{l_C}(p) = 0$, so $d_r^{l_E}(p) = d$. Since an elliptic curve cannot have a meromorphic function with a single pole, it follows that $d_{r-1}^{l_E}(p) \leq d-2$ and this implies $\alpha^{l_C}(p) \geq (0, 1, \dots, 1)$, i.e. l_C has a cusp at p . Thus, if we introduce the notation

$$\mathcal{C}_{g-1,d}^r(0, 1, \dots, 1) = \{[C, p] \in \mathcal{C}_{g-1} : G_d^r(C, (p, (0, 1, \dots, 1))) \neq \emptyset\},$$

then $Y \subseteq \overline{\beta(\mathcal{C}_{g-1,d}^r(0, 1, \dots, 1) \times \mathcal{C}_1)}$. On the other hand, it is known (cf. [EH2]) that $\mathcal{C}_{g-1,d}^r(0, 1, \dots, 1)$ is irreducible of dimension $3g-6$ (that is, codimension 1 in \mathcal{C}_{g-1}), so we must have $Y = \overline{\beta(\mathcal{C}_{g-1,d}^r(0, 1, \dots, 1) \times \mathcal{C}_1)}$, which not only proves that $\overline{\mathcal{M}}_{g,d}^r \cap \Delta_1$ is irreducible, but also determines the intersection. \square

5 The Kodaira dimension of \mathcal{M}_{23}

In this section we prove that $\kappa(\mathcal{M}_{23}) \geq 2$ and we investigate closely the multicanonical linear systems on $\overline{\mathcal{M}}_{23}$. We now describe the three multicanonical Brill-Noether divisors from Section 2.

5.1 The divisor $\overline{\mathcal{M}}_{12}^1$

There is a stratification of \mathcal{M}_{23} given by gonality:

$$\mathcal{M}_2^1 \subseteq \mathcal{M}_3^1 \subseteq \dots \subseteq \mathcal{M}_{12}^1 \subseteq \mathcal{M}_{23}.$$

For $2 \leq d \leq g/2 + 1$ one knows that $\mathcal{M}_k^1 = \mathcal{M}_{g,k}^1$ is an irreducible variety of dimension $2g + 2d - 5$. The general point of $\mathcal{M}_{g,d}^1$ corresponds to a curve having a unique \mathfrak{g}_d^1 .

5.2 The divisor $\overline{\mathcal{M}}_{17}^2$

The Severi variety $V_{d,g}$ of irreducible plane curves of degree d and geometric genus g , where $0 \leq g \leq \binom{d-1}{2}$, is an irreducible subscheme of $\mathbb{P}^{d(d+3)/2}$ of dimension $3d + g - 1$ (cf. [H], [Mod]). Inside $V_{d,g}$ we consider the open dense subset $U_{d,g}$ of irreducible plane curves of degree d having exactly $\delta = \binom{d-1}{2} - g$ nodes and no other singularities. There is a global normalization map

$$m : U_{d,g} \rightarrow \mathcal{M}_g, \quad m([Y]) := [\tilde{Y}], \quad \tilde{Y} \text{ is the normalization of } Y.$$

When $d - 2 \leq g \leq \binom{d-1}{2}$, $d \geq 5$, $U_{d,g}$ has the expected number of moduli, i.e.

$$\dim m(U_{d,g}) = \min(3g - 3, 3g - 3 + \rho(g, 2, d)).$$

In our case we can summarize this as follows:

Proposition 5.1 *There is exactly one component of \mathcal{G}_{17}^2 mapping dominantly to \mathcal{M}_{17}^2 . The general element $(C, l) \in \mathcal{G}_{17}^2$ corresponds to a curve C of genus 23, together with a \mathfrak{g}_{17}^2 which provides a plane model for C of degree 17 with 97 nodes.*

5.3 The divisor $\overline{\mathcal{M}}_{20}^3$

Here we combine the result of Eisenbud and Harris (see [EH2]) about the uniqueness of divisorial components of \mathcal{G}_d^r when $\rho(g, r, d) = -1$, with Sernesi's (see [Se2]) which asserts the existence of components of the Hilbert scheme $H_{d,g}$ parametrizing curves in \mathbb{P}^3 of degree d and genus g with the expected number of moduli, for $d - 3 \leq g \leq 3d - 18$, $d \geq 9$.

Proposition 5.2 *There is exactly one component of \mathcal{G}_{20}^3 mapping dominantly to \mathcal{M}_{20}^3 . The general point of this component corresponds to a pair (C, l) where C is a curve of genus 23 and l is a very ample \mathfrak{g}_{20}^3 .*

We are going to prove that the Brill-Noether divisors $\overline{\mathcal{M}}_{12}^1, \overline{\mathcal{M}}_{17}^2$ and $\overline{\mathcal{M}}_{20}^3$ are mutually distinct.

Theorem 2 *There exists a smooth curve of genus 23 having a \mathfrak{g}_{17}^2 , but no \mathfrak{g}_{20}^3 's. Equivalently, one has $\text{supp}(\mathcal{M}_{17}^2) \not\subseteq \text{supp}(\mathcal{M}_{20}^3)$.*

Proof: It suffices to construct a reducible curve X of compact type of genus 23, which has a smoothable limit \mathfrak{g}_{17}^2 , but no limit \mathfrak{g}_{20}^3 . If $[C] \in \mathcal{M}_{23}$ is a nearby smoothing of X which preserves the \mathfrak{g}_{17}^2 , then $[C] \in \mathcal{M}_{17}^2 - \mathcal{M}_{20}^3$. Let us consider the following curve:

$$X := C_1 \cup C_2 \cup E,$$

where (C_1, p_1) and (C_2, p_2) are general pointed curves of genus 11, E is an elliptic curve, and $p_1 - p_2$ is a primitive 9-torsion point in $\text{Pic}^0(E)$

Step 1) *There is no limit \mathfrak{g}_{20}^3 on X .* Assume that l is a limit \mathfrak{g}_{20}^3 on X . By the additivity of the Brill-Noether number,

$$-1 \geq \rho(l_{C_1}, p_1) + \rho(l_{C_2}, p_2) + \rho(l_E, p_1, p_2).$$

Since (C_i, p_i) are general points in \mathcal{C}_{11} , it follows from Prop.3.2 that $\rho(l_{C_i}, p_i) \geq 0$, hence $\rho(l_E, p_1, p_2) \leq -1$. On the other hand $\rho(l_E, p_1, p_2) \geq -3$ from Prop.4.1.

Denote by (a_0, a_1, a_2, a_3) the vanishing sequence of l_E at p_1 , and by (b_0, b_1, b_2, b_3) that of l_E at p_2 . The condition (8) for a general pointed curve $[(C_i, p_i)] \in \mathcal{C}_{11}$ to possess a \mathfrak{g}_{20}^3 with prescribed ramification at the point p_i and the compatibility conditions between l_{C_i} and l_E at p_i give that:

$$(14 - a_3)_+ + (13 - a_2)_+ + (12 - a_1)_+ + (11 - a_0)_+ \leq 11, \quad (9)$$

and

$$(14 - b_3)_+ + (13 - b_2)_+ + (12 - b_1)_+ + (11 - b_0)_+ \leq 11. \quad (10)$$

1st case: $\rho(l_E, p_1, p_2) = -3$. Then $a_i + b_{3-i} = 20$, for $i = 0, \dots, 3$ and it immediately follows that $20(p_1 - p_2) \sim 0$ in $\text{Pic}^0(E)$, a contradiction.

2nd case: $\rho(l_E, p_1, p_2) = -2$. We have two distinct possibilities here: i) $a_0 + b_3 = 20, a_1 + b_2 = 20, a_2 + b_1 = 20, a_3 + b_0 = 19$. Then it follows that $a^{l_E}(p_1) = (0, 9, 18, 19)$ and $a^{l_E}(p_2) = (0, 2, 11, 20)$, while according to (9), $a_3 \leq 15$, (because $\rho(l_{C_1}, p_1) \leq 1$), a contradiction. ii) $a_0 + b_3 = 20, a_1 + b_2 = 20, a_2 + b_1 = 19, a_3 + b_0 = 20$. Again, it follows that $a_3 = a_0 + 18 \geq 15$, a contradiction.

3rd case: $\rho(l_E, p_1, p_2) = -1$. Then $\rho(l_{C_i}, p_i) = 0$ and l is a refined limit \mathfrak{g}_{20}^3 . From (9) and (10) we must have: $a^{l_E}(p_i) \leq (11, 12, 13, 14)$, $i = 1, 2$. There are four possibilities: i) $a_0 + b_3 = a_1 + b_2 = 20, a_2 + b_1 = a_3 + b_0 = 19$. Then $a_1 = a_0 + 9 \leq 12$, so $b_3 = 20 - a_0 \geq 17$, a contradiction. ii) $a_0 + b_3 = a_2 + b_1 = 20, a_1 + b_2 = a_3 + b_0 = 19$. Then $b_3 = 20 - a_0 \leq 14$, so $a_2 = a_0 + 9 \geq 15$, a contradiction. iii) $a_0 + b_3 = a_3 + b_0 = 20, a_1 + b_2 = a_2 + b_1 = 19$. Then $b_3 = 19 - a_0 \leq 14$, so $a_3 \geq a_0 + 9 \geq 15$, a contradiction. iv) $a_0 + b_3 = a_3 + b_0 = 19, a_1 + b_2 = a_2 + b_1 = 20$. Then $b_3 = 19 - a_0 \leq 14$, so $a_2 \geq a_1 + 9 \geq 15$, a contradiction again. We conclude that X has no limit \mathfrak{g}_{20}^3 .

Step 2) *There exists a smoothable limit \mathfrak{g}_{17}^2 on X , hence $[X] \in \overline{\mathcal{M}}_{17}^2$.* We construct a limit linear series l of type \mathfrak{g}_{17}^2 on X , aspect by aspect: on C_i take $l_{C_i} \in G_{17}^2(C_i)$ such that $a^{l_{C_i}}(p_i) = (4, 9, 13)$. Note that in this case $\sum_{j=0}^r (\alpha_j + g - d + r)_+ = g$, so (8) ensures the existence of such a \mathfrak{g}_{17}^2 . On E we take $l_E = |V_E|$, where $|V_E| \subseteq |4p_1 + 13p_2| = |4p_2 + 13p_1|$ is a \mathfrak{g}_{17}^2 with vanishing sequence $(4, 8, 13)$ at p_i . Prop.4.1 ensures the existence of such a linear series. In this way l is a refined limit \mathfrak{g}_{17}^2 on X with $\rho(l_{C_i}, p_i) = 0, \rho(l_E, p_1, p_2) = -1$. We prove that l is dimensionally proper. Let $\pi_i : \mathcal{C}_i \rightarrow \Delta_i$, $\tilde{p}_i : \Delta_i \rightarrow \mathcal{C}_i$, be the versal deformation of $[(C_i, p_i)] \in \mathcal{C}_{11}$, and $\sigma_i : \mathcal{G}_{17}^2(\mathcal{C}_i/\Delta_i, (\tilde{p}_i, (4, 8, 11))) \rightarrow \Delta_i$ the projection.

Since being general is an open condition, we have that σ_i is surjective and $\dim \sigma_i^{-1}(t) = \rho(l_{C_i}, p_i) = 0$, for each $t \in \Delta_i$, therefore

$$\dim \mathcal{G}_{17}^2(\mathcal{C}_i/\Delta_i, (\tilde{p}_i, (4, 8, 11))) = \dim \Delta_i + \rho(l_{C_i}, p_i) = 31.$$

Next, let $\pi : \mathcal{C} \rightarrow \Delta$, $\tilde{p}_1, \tilde{p}_2 : \Delta \rightarrow \mathcal{C}$ be the versal deformation of (E, p_1, p_2) . We prove that

$$\dim \mathcal{G}_{17}^2(\mathcal{C}/\Delta, (\tilde{p}_i, (4, 7, 11))) = \dim \Delta + \rho(l_E, p_1, p_2) = 1.$$

This follows from Prop.4.1, since a 2-pointed elliptic curve $(E_t, \tilde{p}_1(t), \tilde{p}_2(t))$ has at most one \mathfrak{g}_{17}^2 with ramification $(4, 7, 11)$ at both $\tilde{p}_1(t)$ and $\tilde{p}_2(t)$, and exactly one when $9(\tilde{p}_1(t) - \tilde{p}_2(t)) \sim 0$. Hence $\text{Im} \mathcal{G}_{17}^2(\mathcal{C}/\Delta, (\tilde{p}_i, (4, 7, 11))) = \{t \in \Delta : 9(\tilde{p}_1(t) - \tilde{p}_2(t)) \sim 0 \text{ in } \text{Pic}^0(E_t)\}$, which is a divisor on Δ , so the claim follows and l is a dimensionally proper \mathfrak{g}_{17}^2 . \square

A slight variation of the previous argument gives us:

Proposition 5.3 *We have $\text{supp}(\overline{\mathcal{M}}_{17}^2 \cap \Delta_1) \neq \text{supp}(\overline{\mathcal{M}}_{20}^3 \cap \Delta_1)$.*

Proof: We construct a curve $[Y] \in \Delta_1 \subseteq \overline{\mathcal{M}}_{23}$ which has a smoothable limit \mathfrak{g}_{17}^2 but no limit \mathfrak{g}_{20}^3 . Let us consider the following curve:

$$Y := C_1 \cup C_2 \cup E_1 \cup E,$$

where (C_2, p_2) is a general point of \mathcal{C}_{11} , (C_1, p_1, x) is a general 2-pointed curve of genus 10, (E_1, x) is general in \mathcal{C}_1 , E is an elliptic curve, and $p_1 - p_2 \in \text{Pic}^0(E)$ is a primitive 9-torsion. In order to prove that Y has no limit \mathfrak{g}_{20}^3 , one just has to take into account that according to Prop.3.3, the condition for a general 1-pointed curve (C, z) of genus g , to have a \mathfrak{g}_d^r with ramification α at z is the same with the condition for a general 2-pointed curve (D, x, y) of genus $g - 1$ to have a \mathfrak{g}_d^r with ramification α at x and a cusp at y . Therefore we can repeat what we did in the proof of Theorem 2. Next, we construct l , a smoothable limit \mathfrak{g}_{17}^2 on Y : take $l_{C_2} \in G_{17}^2(C_2, (p_2, (4, 8, 11)))$, $l_E = |V_E| \subseteq |4p_1 + 13p_2|$, with $\alpha^{l_E}(p_i) = (4, 7, 11)$, on E_1 take $l_{E_1} = 14x + |3x|$, and finally on C_1 take l_{C_1} such that $\alpha^{l_{C_1}}(p_1) = (4, 8, 11)$, $\alpha^{l_{C_1}}(x) = (0, 0, 1)$. Prop.3.3 ensures the existence of l_{C_1} . Clearly, l is a refined limit \mathfrak{g}_{17}^2 and the proof that it is smoothable is all but identical to the one in the last part of Theorem 2. \square

The other cases are settled by the following:

Theorem 3 *There exists a smooth curve of genus 23 having a \mathfrak{g}_{12}^1 but having no \mathfrak{g}_{17}^2 nor \mathfrak{g}_{20}^3 . Equivalently, $\text{supp}(\mathcal{M}_{12}^1) \not\subseteq \text{supp}(\mathcal{M}_{17}^2)$ and $\text{supp}(\mathcal{M}_{12}^1) \not\subseteq \text{supp}(\mathcal{M}_{20}^3)$.*

Proof: We take the curve considered in [EH3]:

$$Y := C_1 \cup C_2 \cup E,$$

where (C_i, p_i) are general points of \mathcal{C}_{11} , E is elliptic and $p_1 - p_2 \in \text{Pic}^0(E)$ is a primitive 12-torsion. Clearly Y has a (smoothable) limit \mathfrak{g}_{12}^1 : on C_i take the pencil $|12p_i|$, while on E take the pencil spanned by $12p_1$ and $12p_2$. It is proved in [EH3] that Y has no limit \mathfrak{g}_{17}^2 's and similarly one can prove that Y has no limit \mathfrak{g}_{20}^3 's either. We omit the details. \square

Now we are going to prove that equation (2)

$$\text{supp}(\mathcal{M}_{12}^1) \cap \text{supp}(\mathcal{M}_{17}^2) = \text{supp}(\mathcal{M}_{17}^2) \cap \text{supp}(\mathcal{M}_{20}^3) = \text{supp}(\mathcal{M}_{20}^3) \cap \text{supp}(\mathcal{M}_{12}^1)$$

is impossible, and as explained before, this will imply that $\kappa(\mathcal{M}_{23}) \geq 2$. The main step in this direction is the following:

Proposition 5.4 *There exists a stable curve of compact type of genus 23 which has a smoothable limit \mathfrak{g}_{20}^3 , a smoothable limit \mathfrak{g}_{15}^2 (therefore also a \mathfrak{g}_{17}^2), but has generic gonality, that is, it does not have any limit \mathfrak{g}_{12}^1 .*

Proof We shall consider the following stable curve X of genus 23:

$$X := \Gamma \cup E_1 \cup \dots \cup E_8,$$

where the E_i 's are elliptic curves, $\Gamma \subseteq \mathbb{P}^2$ is a general smooth plane septic and the points of attachment $\{p_i\} = \Gamma \cup E_i$ are general points of Γ .

Step 1) *There is no limit \mathfrak{g}_{12}^1 on X .* Assume that l is a limit \mathfrak{g}_{12}^1 on X . Since the elliptic curves E_i cannot have meromorphic functions with a single pole, we have that $a^{l_{E_i}}(p_i) \leq (10, 12)$, hence $\alpha^{l_\Gamma}(p_i) \geq (0, 1)$, that is, l_Γ has a cusp at p_i for $i = 1, \dots, 8$. We now prove that Γ has no \mathfrak{g}_{12}^1 's with cusps at the points p_i .

First, we notice that $\dim G_{12}^1(\Gamma) = \rho(15, 1, 12) = 7$. Indeed, if we assume that $\dim G_{12}^1(\Gamma) \geq 8$, by applying Keem's Theorem (cf. [ACGH], p.200) we would get that Γ possesses a \mathfrak{g}_4^1 , which is impossible since $\text{gon}(\Gamma) = 6$. (In general, if $Y \subseteq \mathbb{P}^2$ is a smooth plane curve, $\deg(Y) = d$, then $\text{gon}(Y) = d - 1$, and the \mathfrak{g}_{d-1}^1 computing the gonality is cut out by the lines passing through a point $p \in Y$, see [ACGH].) Next, we define the variety

$$\Sigma = \{(l, q_1, \dots, q_8) \in G_{12}^1(\Gamma) \times \Gamma^8 : \alpha^l(q_i) \geq (0, 1), i = 1, \dots, 8\}$$

and denote by $\pi_1 : \Sigma \rightarrow G_{12}^1(\Gamma)$ and $\pi_2 : \Sigma \rightarrow \Gamma^8$ the two projections. For any $l \in G_{12}^1(\Gamma)$, the fibre $\pi_1^{-1}(l)$ is finite, hence $\dim \Sigma = \dim G_{12}^1(\Gamma) = 7$, which shows that π_2 cannot be surjective and this proves our claim.

Step 2) *There exists a smoothable limit \mathfrak{g}_{17}^2 on X , hence $[X] \in \overline{\mathcal{M}}_{17}^2$.* We construct l , a limit \mathfrak{g}_{17}^2 on X as follows: on Γ there is a (unique) \mathfrak{g}_7^2 , and we consider $l_\Gamma = \mathfrak{g}_7^2(p_1 + \dots + p_8)$, i.e. the Γ -aspect l_Γ is obtained from the \mathfrak{g}_7^2 by adding the base points p_1, \dots, p_8 . Clearly $a^{l_\Gamma}(p_i) = (1, 2, 3)$ for each i . On E_i we take $l_{E_i} = \mathfrak{g}_3^2(12p_i)$ for $i = 1, \dots, 8$, where \mathfrak{g}_3^2 is a complete linear series of the form $|2p_i + x_i|$, with $x_i \in E_i - \{p_i\}$. Furthermore, $a^{l_{E_i}}(p_i) = (12, 13, 14)$, so $l = \{l_\Gamma, l_{E_i}\}$ is a refined limit \mathfrak{g}_{15}^2 on X . One sees that $\rho(l_{E_i}, \alpha^{l_{E_i}}(p_i)) = 1$ for all i , $\rho(l_\Gamma, \alpha^{l_\Gamma}(p_1), \dots, \alpha^{l_\Gamma}(p_8)) = -15$, and $\rho(l) = -7$. We now prove that l is dimensionally proper.

Let $\pi_i : \mathcal{C}_i \rightarrow \Delta_i$, $\tilde{p}_i : \Delta_i \rightarrow \mathcal{C}_i$ be the versal deformation space of (E_i, p_i) , for $i = 1, \dots, 8$. There is an obvious isomorphism over Δ_i

$$\mathcal{G}_{15}^2(\mathcal{C}_i/\Delta_i, (\tilde{p}_i, (12, 12, 12))) \simeq \mathcal{G}_3^2(\mathcal{C}_i/\Delta_i, (\tilde{p}_i, 0)).$$

If $\sigma_i : \mathcal{G}_3^2(\mathcal{C}_i/\Delta_i, (\tilde{p}_i, 0)) \rightarrow \Delta_i$ is the natural projection, then for each $t \in \Delta_i$, the fibre $\sigma_i^{-1}(t)$ is isomorphic to $\pi_i^{-1}(t)$, the isomorphism being given by

$$\pi_i^{-1}(t) \ni q \mapsto |2\tilde{p}_i(t) + q| \in G_3^2(\pi_i^{-1}(t)).$$

Thus, $\mathcal{G}_3^2(\mathcal{C}_i/\Delta_i, (\tilde{p}_i, 0))$ is a smooth irreducible surface, which shows that l is dimensionally proper w.r.t. E_i . Next, let us consider $\pi : \mathcal{X} \rightarrow \Delta$, $\tilde{p}_1, \dots, \tilde{p}_8 : \Delta \rightarrow \mathcal{X}$, the versal deformation of $(\Gamma, p_1, \dots, p_8)$. We have to prove that

$$\dim \mathcal{G}_{15}^2(\mathcal{X}/\Delta, (\tilde{p}_i, (1, 1, 1))) = \dim \Delta + \rho(l_\Gamma, \alpha^{l_\Gamma}(p_i)) = 35.$$

There is an isomorphism over Δ ,

$$\mathcal{G}_{15}^2(\mathcal{X}/\Delta, (\tilde{p}_i, (1, 1, 1))) \simeq \mathcal{G}_7^2(\mathcal{X}/\Delta, (\tilde{p}_i, 0)).$$

If $\pi_0 : \mathcal{C} \rightarrow \mathcal{M}$ is the versal deformation space of Γ , then we denote by $\mathcal{G}_7^2 \rightarrow \mathcal{M}$ the scheme parametrizing \mathfrak{g}_7^2 's on curves of genus 15 'nearby' Γ (See Section 3 for this notation). Clearly $\mathcal{G}_7^2(\mathcal{X}/\Delta, (\tilde{p}_i, 0)) \simeq \mathcal{G}_7^2 \times_{\mathcal{M}} \Delta$, so it suffices to prove that \mathcal{G}_7^2 has the expected dimension at the point $(\Gamma, \mathfrak{g}_7^2)$. For this we use Prop. 3.1. We have that $N_{\Gamma/\mathbb{P}^2} = \mathcal{O}_\Gamma(7)$, $K_\Gamma = \mathcal{O}_\Gamma(4)$, hence

$$H^1(\Gamma, N_{\Gamma/\mathbb{P}^2}) \simeq H^0(\Gamma, \mathcal{O}_\Gamma(-3))^\vee = 0,$$

so l is dimensionally proper w.r.t. Γ as well. We conclude that l is smoothable.

Step 3) *There exists a smoothable limit \mathfrak{g}_{20}^3 on X , that is $[X] \in \overline{\mathcal{M}}_{20}^3$.* First we notice that there is an isomorphism $\Gamma \xrightarrow{\sim} G_6^1(\Gamma)$, given by

$$\Gamma \ni p \mapsto |\mathfrak{g}_7^2 - p| \in G_6^1(\Gamma).$$

Consequently, there is a 2-dimensional family of \mathfrak{g}_{12}^3 's on Γ , of the form $\mathfrak{g}_{12}^3 = \mathfrak{g}_6^1 + \mathfrak{h}_6^1 = |2\mathfrak{g}_7^2 - p - q|$, where $p, q \in \Gamma$. Pick $l_0 = l'_0 + l''_0$, with $l'_0, l''_0 \in G_6^1(\Gamma)$, a general \mathfrak{g}_{12}^3 of this type.

We construct l , a limit \mathfrak{g}_{20}^3 on X , as follows: the Γ -aspect is given by $l_\Gamma = l_0(p_1 + \cdots + p_8)$, and because of the generality of the chosen l_0 we have that $\rho(l_\Gamma, \alpha^{l_\Gamma}(p_1), \dots, \alpha^{l_\Gamma}(p_8)) = -9$. The E_i -aspect is given by $l_{E_i} = \mathfrak{g}_4^3(16p_i)$, where $\mathfrak{g}_4^3 = |3p_i + x_i|$, with $x_i \in E_i - \{p_i\}$, for $i = 1, \dots, 8$. It is clear that $\rho(l_{E_i}, \alpha^{l_{E_i}}(p_i)) = 1$ and that $l' = \{l_\Gamma, l_{E_i}\}$ is a refined limit \mathfrak{g}_{20}^3 on X .

In order to prove that l' is dimensionally proper, we first notice that l' is dimensionally proper w.r.t. the elliptic tails E_i . We now prove that l' is dimensionally proper w.r.t. Γ . As in the previous step, we consider $\pi : \mathcal{X} \rightarrow \Delta$, $\tilde{p}_1, \dots, \tilde{p}_8 : \Delta \rightarrow \mathcal{X}$, the versal deformation of $(\Gamma, p_1, \dots, p_8)$ and $\pi_0 : \mathcal{C} \rightarrow \mathcal{M}$, the versal deformation space of Γ . There is an isomorphism over Δ

$$\mathcal{G}_{20}^3(\mathcal{X}/\Delta, (\tilde{p}_1, \alpha^{l_\Gamma}(p_1), \dots, (\tilde{p}_8, \alpha^{l_\Gamma}(p_8)))) \simeq \mathcal{G}_{12}^3(\mathcal{C}/\mathcal{M}) \times_{\mathcal{M}} \Delta.$$

It suffices to prove that $\mathcal{G}_{12}^3 = \mathcal{G}_{12}^3(\mathcal{C}/\mathcal{M})$ has a component of the expected dimension passing through (Γ, l_0) . In this way, the genus 23 problem is turned into a deformation theoretic problem in genus 15. Denote as usual by $\sigma : \mathcal{G}_{12}^3 \rightarrow \mathcal{M}$ the natural projection. According to Prop.3.1, it will be enough to exhibit an element $(C, l) \in \mathcal{G}_{20}^3$, sitting in the same component as (Γ, l_0) , such that the linear system l is base point free and simple, and if $\phi : C \rightarrow \mathbb{P}^3$ is the map induced by l , then $H^1(C, N_\phi) = 0$. Certainly we cannot take C to be a smooth plane septic because in this case $H^1(C, N_\phi) \neq 0$, as one can easily see. Instead, we consider the 6-gonal locus in a neighbourhood of the point $[\Gamma] \in \mathcal{M}_{15}$, or equivalently, the 6-gonal locus in \mathcal{M} , the versal deformation space of Γ . One has the projection $\mathcal{G}_6^1 \rightarrow \mathcal{M}$, and the scheme \mathcal{G}_6^1 is smooth (and irreducible) of dimension $37(= 2g + 2d - 5; g = 15, d = 6)$. We denote by

$$\mu : \mathcal{G}_6^1 \times_{\mathcal{M}} \mathcal{G}_6^1 \rightarrow \mathcal{M}, \quad \mu([C, l, l']) = [C].$$

Let us pick a component $\mathcal{X} \subseteq \mathcal{G}_6^1 \times_{\mathcal{M}} \mathcal{G}_6^1$ such that $(\Gamma, l'_0, l''_0) \in \mathcal{X}$. The general point of \mathcal{X} corresponds to a curve C with two base-point-free pencils $l', l'' \in G_6^1(C)$ such that if $f' : C \rightarrow \mathbb{P}^1$ and $f'' : C \rightarrow \mathbb{P}^1$ are the corresponding morphisms, then

$$\phi = (f', f'') : C \rightarrow \mathbb{P}^1 \times \mathbb{P}^1$$

is birational. We denote by $\eta : \mathcal{X} \rightarrow \mathcal{G}_{12}^3$, the map given by $\eta(C, l', l'') := (C, l' + l'')$. The fact that η is well-defined follows from the base-point-free-pencil-trick. There is a stratification of \mathcal{M} given by the number of pencils: for $i \geq 0$ we define,

$$\mathcal{M}(i)^0 := \{[C] \in \mathcal{M} : C \text{ possesses } i \text{ mutually independent, base-point-free } \mathfrak{g}_6^1\text{'s}\},$$

and $\mathcal{M}(i) := \overline{\mathcal{M}(i)^0}$. The strata $\mathcal{M}(i)^0$ are constructible subsets of \mathcal{M} , the first stratum $\mathcal{M}(1) = \text{Im}(\mathcal{G}_6^1)$ is just the 6-gonal locus; the stratum $\mathcal{M}(2)$ is irreducible and $\dim \mathcal{M}(2) = g + 4d - 7 = 32$ (cf. [AC1]). We denote by $\mathcal{M}_{sept} := \overline{m(U_{7,15}) \cap \mathcal{M}}$, the closure of the locus of smooth plane septics in \mathcal{M} , and by $\mathcal{M}_{oct} := \overline{m(U_{8,15}) \cap \mathcal{M}}$, the locus of curves which are normalizations of plane octics with 6 nodes. Since the Severi varieties $U_{7,15}$ and $U_{8,15}$ are irreducible, so are the loci \mathcal{M}_{sept} and \mathcal{M}_{oct} . Furthermore $\dim \mathcal{M}_{sept} = 27$ and $\dim \mathcal{M}_{oct} = 30$. We prove that $\mathcal{M}_{sept} \subseteq \mathcal{M}_{oct}$, hence $\mathcal{M}_{oct} \subseteq \mu(\mathcal{X})$. Indeed, let us pick $Y \subseteq \mathbb{P}^2$ a smooth plane septic, and $L \subseteq \mathbb{P}^2$ a general

line, $L.Y = p_1 + \dots + p_7$. Denote $X := C \cup L$, $\deg(X) = 8$, $p_a(X) = 21$. We consider the node p_7 unassigned, while p_1, \dots, p_6 are assigned. By using [Ta] Theorem 2.13, there exists a flat family of plane curves $\pi : \mathcal{X} \rightarrow B$ and a point $0 \in B$, such that $X_0 = \pi^{-1}(0) = X$, while for $0 \neq b \in B$, the fibre X_b is an irreducible octic with nodes $p_1(b), \dots, p_6(b)$, and such that $p_i(b) \rightarrow p_i$, when $b \rightarrow 0$, for $i = 1, \dots, 6$. If $\mathcal{X}' \rightarrow B$ is the family resulting by normalizing the surface \mathcal{X} , and $\eta : \mathcal{X}'' \rightarrow B$ is the stable family associated to the semistable family $\mathcal{X}' \rightarrow B$, then we get that $\eta^{-1}(0) = Y$, while $\eta^{-1}(b)$ is the normalization of X_b for $b \neq 0$. This proves our contention.

We are going to show that given a general point $[C] \in \mathcal{M}_{oct}$, and $(C, l, l') \in \mu^{-1}([C])$, the condition $H^1(C, N_\phi) = 0$ is satisfied, hence \mathcal{G}_{12}^3 is smooth of the expected dimension at the point $(C, l + l')$. This will prove the existence of a component of \mathcal{G}_{12}^3 passing through (Γ, l_0) and having the expected dimension. We take $\overline{C} \subseteq \mathbb{P}^2$, a general point of $U_{8,15}$, with nodes $p_1, \dots, p_6 \in \mathbb{P}^2$ in general position. Theorem 3.2 from [AC1] ensures that there exists a plane octic having 6 prescribed nodes in general position. Let $\nu : C \rightarrow \overline{C}$ be the normalization map, $\nu^{-1}(p_i) = q'_i + q''_i$ for $i = 1, \dots, 6$. Choose two nodes, say p_1 and p_2 , and denote by $\mathfrak{g}_6^1 = |H - q'_1 - q''_1|$ and $\mathfrak{h}_6^1 = |H - q'_2 - q''_2|$, the linear series obtained by projecting \overline{C} from p_1 and p_2 respectively. Here $H \in |\nu^* \mathcal{O}_{\mathbb{P}^2}(1)|$ is an arbitrary line section of C . The morphism induced by $(\mathfrak{g}_6^1, \mathfrak{h}_6^1)$ is denoted by $\phi : C \rightarrow \mathbb{P}^1 \times \mathbb{P}^1$, and $\phi_1 = s \circ \phi : C \rightarrow \mathbb{P}^3$, with $s : \mathbb{P}^1 \times \mathbb{P}^1 \rightarrow \mathbb{P}^3$ the Segre embedding. There is an exact sequence over C

$$0 \longrightarrow N_\phi \longrightarrow N_{\phi_1} \longrightarrow \phi^* N_{\mathbb{P}^1 \times \mathbb{P}^1 / \mathbb{P}^3} \longrightarrow 0. \quad (11)$$

We can argue as in [AC2] p.473, that for a general $(C, \mathfrak{g}_6^1, \mathfrak{h}_6^1)$ with $[C] \in \mathcal{M}_{oct}$, we have $h^1(C, N_\phi) = 0$. Indeed, let us denote by \mathcal{X}_0 the open set of \mathcal{X} corresponding to points (X, l, l') such that $\chi : X \rightarrow \mathbb{P}^1 \times \mathbb{P}^1$, the morphism associated to the pair of pencils (l, l') is birational, and by $\mathcal{U} \subseteq \mathcal{X}_0$ the variety of those points $(X, l, l') \in \mathcal{X}_0$ such that $H^1(X, N_\chi) \neq 0$. Define

$$\mathcal{V} := \{x = (X, l, l', \mathcal{F}, \mathcal{F}') : (X, l, l') \in \mathcal{U}, \mathcal{F} \text{ is a frame for } l, \mathcal{F}' \text{ is a frame for } l'\}.$$

We may assume that for a generic $x \in \mathcal{U}$, the corresponding pencils l and l' are base-point-free. Suppose that \mathcal{U} has a component of dimension α . For any $x \in \mathcal{V}$,

$$T_x(\mathcal{V}) \subseteq H^0(X, N_\chi), \text{ and } \dim T_x(\mathcal{V}) \geq \alpha + 2 \dim PGL(2) = \alpha + 6.$$

If \mathcal{K}_χ is the cuspidal sheaf of χ and $N'_\chi = N_\chi / \mathcal{K}_\chi$, then according to [AC1] Lemma 1.4, for a general point $x \in \mathcal{V}$ one has that,

$$T_x(\mathcal{V}) \cap H^0(X, \mathcal{K}_\chi) = \emptyset,$$

from which it follows that $\alpha \leq g - 6$. If not, one would have that $h^0(X, N'_\chi) \geq g + 1$, and therefore by Clifford's Theorem, $h^1(X, N_\chi) = h^1(X, N'_\chi) = 0$, which contradicts the definition of \mathcal{U} . Since clearly $\dim \mathcal{M}_{oct} > g - 6$, we can assume that $h^1(C, N_\phi) = 0$, for the general $[C] \in \mathcal{M}_{oct}$. Therefore, by taking cohomology in (11), we get that

$$H^1(C, N_{\phi_1}) = H^1(C, \mathcal{O}_C(2)),$$

where $\mathcal{O}_C(1) = \phi_1^* \mathcal{O}_{\mathbb{P}^3}(1)$. By Serre duality,

$$H^1(C, \mathcal{O}_C(2)) = 0 \iff |K_C - 2\mathfrak{g}_6^1 - 2\mathfrak{h}_6^1| = \emptyset. \quad (12)$$

Since $K_C = 5H - \sum_{i=1}^6 (q'_i + q''_i)$, equation (12) becomes

$$|H + q'_1 + q''_1 + q'_2 + q''_2 - \sum_{i=3}^6 (q'_i + q''_i)| = \emptyset. \quad (13)$$

If $L = \overline{p_1 p_2} \subseteq \mathbb{P}^2$, we can write $\nu^*(L) = q'_1 + q''_1 + q'_2 + q''_2 + x + y + z + t$, and (13) is rewritten as

$$|2H - x - y - z - t - \sum_{i=3}^6 (q'_i + q''_i)| = \emptyset.$$

So, one has to show that there are no conics passing through the nodes p_3, p_4, p_5 and p_6 and also through the points in $L \cdot \overline{C} - 2p_1 - 2p_2$. Because $[\overline{C}] \in U_{8,15}$ is general we may assume that x, y, z and t are distinct, smooth points of \overline{C} . Indeed, if the divisor $x + y + z + t$ on \overline{C} does not consist of distinct points, or one of its points is a node, we obtain that \overline{C} has intersection number 8 with the line L at 5 points or less. But according to [DH], the locus in the Severi variety

$$\{[X] \in U_{d,g} : X \text{ has total intersection number } m + 3 \text{ with a line at } m \text{ points} \}$$

is a divisor on $U_{d,g}$, so we may assume that $[\overline{C}]$ lies outside this divisor. Now, if x, y, z and t are distinct and smooth points of \overline{C} , a conic satisfying (13) would necessarily be a degenerate one, and one gets a contradiction with the assumption that the nodes p_1, \dots, p_6 of \overline{C} are in general position. \square

Remark: We have a nice geometric characterization of some of the strata \mathcal{M}_i . First, by using Zariski's Main Theorem for the birational projection $\mathcal{G}_6^1 \rightarrow \mathcal{M}(1)$, one sees that $[C] \in \mathcal{M}(1)_{\text{sing}}$ if and only if either $[C] \in \mathcal{M}(2)^0$, or C possesses a \mathfrak{g}_6^1 such that $\dim |2\mathfrak{g}_6^1| \geq 3$. In the latter case, the \mathfrak{g}_6^1 is a specialization of 2 different \mathfrak{g}_6^1 's in some family of curves, hence $\mathcal{M}(2) = \mathcal{M}(1)_{\text{sing}}$ (cf [Co2]). As a matter of fact, Coppens has proved that for $4 \leq k \leq [(g+1)/2]$ and $8 \leq g \leq (k-1)^2$, there exists a k -gonal curve of genus g carrying exactly 2 linear series \mathfrak{g}_k^1 , so the general point of $\mathcal{M}(2)$ corresponds to a curve C of genus 15, having exactly 2 base-point-free \mathfrak{g}_6^1 's. Furthermore, using Coppens' classification of curves having many pencils computing the gonality (see [Co1]), we have that $\mathcal{M}(6) = \mathcal{M}_{\text{oct}}$, and $\mathcal{M}(i) = \mathcal{M}_{\text{sept}}$, for each $i \geq 7$.

Now we are in a position to complete the proof of Theorem 1:

Proof of Theorem 1 According to (2), it will suffice to prove that there exists a smooth curve $[Y] \in \mathcal{M}_{23}$ which carries a \mathfrak{g}_{20}^3 , a \mathfrak{g}_{17}^2 but has no \mathfrak{g}_{12}^1 's. In the proof of Prop.5.4 we constructed a stable curve of compact type $[X] \in \overline{\mathcal{M}}_{23}$ such that $[X] \in \overline{\mathcal{M}}_{17}^2 \cap \overline{\mathcal{M}}_{20}^3$, but $[X] \notin \overline{\mathcal{M}}_{12}^1$. If we prove that $[X] \in \overline{\mathcal{M}}_{17}^2 \cap \overline{\mathcal{M}}_{20}^3$, that is, there are smoothings of X which preserve both the \mathfrak{g}_{17}^2 and the \mathfrak{g}_{20}^3 , we are done. One can write $\overline{\mathcal{M}}_{17}^2 \cap \overline{\mathcal{M}}_{20}^3 = Y_1 \cup \dots \cup Y_s$, where Y_i are irreducible codimension 2 subvarieties of $\overline{\mathcal{M}}_{23}$. Assume that $[X] \in Y_1$. If $Y_1 \cap \mathcal{M}_{23} \neq \emptyset$, then $[X] \in Y_1 = \overline{Y_1} \cap \mathcal{M}_{23} \subseteq \overline{\mathcal{M}}_{17}^2 \cap \overline{\mathcal{M}}_{20}^3$, and the conclusion follows.

So we may assume that $Y_1 \subseteq \overline{\mathcal{M}}_{23} - \mathcal{M}_{23}$. Because $[X] \in \Delta_1 - \bigcup_{j \neq 1} \Delta_j$, we must have $Y \subseteq \Delta_1$. It follows that $\overline{\mathcal{M}}_{17}^2 \cap \Delta_1$ and $\overline{\mathcal{M}}_{20}^3 \cap \Delta_1$ have Y_1 as a common component. According to Prop.4.2, both intersections $\overline{\mathcal{M}}_{17}^2 \cap \Delta_1$ and $\overline{\mathcal{M}}_{20}^3 \cap \Delta_1$ are irreducible, hence $\overline{\mathcal{M}}_{17}^2 \cap \Delta_1 = \overline{\mathcal{M}}_{20}^3 \cap \Delta_1 = Y_1$, which contradicts Prop.5.3. Theorem 1 now follows. \square

6 The slope conjecture and \mathcal{M}_{23}

In this final section we explain how the slope conjecture in the context of \mathcal{M}_{23} implies that $\kappa(\mathcal{M}_{23}) = 2$, and then we present evidence for this.

The slope of $\overline{\mathcal{M}}_g$ is defined as $s_g := \inf \{a \in \mathbb{R}_{>0} : |a\lambda - \delta| \neq \emptyset\}$, where $\delta = \delta_0 + \delta_1 + \dots + \delta_{[g/2]}$, $\lambda \in \text{Pic}(\overline{\mathcal{M}}_g) \otimes \mathbb{R}$. Since λ is big, it follows that $s_g < \infty$. If \mathbb{E} is the cone of effective divisors in $\text{Div}(\overline{\mathcal{M}}_g) \otimes \mathbb{R}$, we define the slope function $s : \mathbb{E} \rightarrow \mathbb{R}$ by the formula

$$s_D := \inf \{a/b : a, b > 0 \text{ such that } \exists c_i \geq 0 \text{ with } [D] = a\lambda - b\delta - \sum_{i=0}^{[g/2]} c_i \delta_i\},$$

for an effective divisor D on $\overline{\mathcal{M}}_g$. Clearly $s_g \leq s_D$ for any $D \in \mathbb{E}$. When $g+1$ is composite, we obtain the estimate $s_g \leq 6 + 12/(g+1)$ by using the Brill-Noether divisors $\overline{\mathcal{M}}_{g,d}^r$, with $\rho(g, r, d) = -1$.

Conjecture 1 ([HMo]) *We have that $s_g \geq 6 + 12/(g+1)$ for each $g \geq 3$, with equality when $g+1$ is composite.*

Harris and Morrison also stated (in a somewhat vague form) that for composite $g+1$, the Brill-Noether divisors not only minimize the slope among all effective divisors, but they also single out those irreducible $D \in \mathbb{E}$ with $s_D = s_g$.

The slope conjecture has been proved for $3 \leq g \leq 11, g \neq 10$ (cf. [HMo], [CR3,4], [Tan]). A strong form of the conjecture holds for $g = 3$ and $g = 5$: on $\overline{\mathcal{M}}_3$ the only irreducible divisor of slope $s_3 = 9$ is the hyperelliptic divisor, while on $\overline{\mathcal{M}}_5$ the only irreducible divisor of slope $s_5 = 8$ is the trigonal divisor (cf. [HMo]). Conjecture 1 would imply that $\kappa(\mathcal{M}_g) = -\infty$ for all $g \leq 22$. For $g = 23$, we rewrite (1) as

$$nK_{\overline{\mathcal{M}}_{23}} = \frac{n}{c_{23,r,d}} [\overline{\mathcal{M}}_{g,d}^r] + 8n\delta_1 + \sum_{i=2}^{11} \frac{(i(23-i)-4)}{2} n\delta_i \quad (n \geq 1), \quad (14)$$

(see Section 2 for the coefficients $c_{g,r,d}$). As Harris and Morrison suggest, we can ask the question whether the class of any $D \in \mathbb{E}$ with $s_D = s_g$ is (modulo a sum of boundary components Δ_i) proportional to $[\overline{\mathcal{M}}_{23,d}^r]$, and whether the sections defining (multiples of) $\overline{\mathcal{M}}_{23,d}^r$ form a maximal algebraically independent subset of the canonical ring $R(\overline{\mathcal{M}}_{23})$. If so, it would mean that the boundary divisor $8n\delta_1 + (1/2) \sum_{i=2}^{11} n(i(23-i)-4)\delta_i$ is a fixed part of $|nK_{\overline{\mathcal{M}}_{23}}|$. Moreover, using our independence result for the three Brill-Noether divisors, it would follow that $h^0(\overline{\mathcal{M}}_{23}, nK_{\overline{\mathcal{M}}_{23}})$ grows quadratically in n , for n sufficiently high and sufficiently divisible, hence $\kappa(\mathcal{M}_{23}) = 2$. We would also have that $\Sigma \cap \mathcal{M}_{23} = \mathcal{M}_{12}^1 \cap \mathcal{M}_{17}^2 \cap \mathcal{M}_{20}^3$, with Σ the common base locus of all the linear systems

$|nK_{\overline{\mathcal{M}}_{23}}|$.

Evidence for these facts is of various sorts: first, one knows (cf. [Ta], [CR3]) that $|nK_{\overline{\mathcal{M}}_{23}}|$ has a large fixed part in the boundary: for each $n \geq 1$, every divisor in $|nK_{\overline{\mathcal{M}}_{23}}|$ must contain Δ_i with multiplicity $16n$ when $i = 1$, $19n$ when $i = 2$, and $(21 - i)n$ for $i = 3, \dots, 9$ or 11 . The results for Δ_1 and Δ_2 are optimal since these multiplicities coincide with those in (14). Note that $[\Delta_1] = 2\delta_1$.

Next, one can show that certain geometric loci in \mathcal{M}_{23} which are contained in all three Brill-Noether divisors, are contained in Σ as well. The method is based on the trivial observation that for a family $f : X \rightarrow B$ of stable curves of genus 23 with smooth general member, if $B.K_{\overline{\mathcal{M}}_{23}} < 0$ (or equivalently, $\text{slope}(X/B) = \delta_B/\lambda_B > 13/2$), then $\phi(B) \subseteq \Sigma$, where $\phi : B \rightarrow \overline{\mathcal{M}}_{23}$, $\phi(b) = [X_b]$, is the associated moduli map. We have that:

- One can fill up the d -gonal locus $\overline{\mathcal{M}}_d^1$ with families $f : X \rightarrow B$ of stable curves of genus g such that $\text{slope}(X/B)$ is $8 + 4/g$ in the hyperelliptic case, $36(g+1)/(5g+1)$ in the trigonal case, and $4(5g+7)/(3g+1)$ in the tetragonal case (cf. [Sta]). For $g = 23$ it follows that $\mathcal{M}_4^1 \subseteq \Sigma$. Note that this result is not optimal if we believe the slope conjecture since we know that $\mathcal{M}_8^1 \subseteq \mathcal{M}_{12}^1 \cap \mathcal{M}_{17}^2 \cap \mathcal{M}_{20}^3$. (The inclusion $\mathcal{M}_8^1 \subseteq \mathcal{M}_{20}^3$ is a particular case of a result from [CM].)
- We take a pencil of nodal plane curves of degree d with f assigned nodes in general position such that $\binom{d-1}{2} - f = 23$, and with b base points, where $4f + b = d^2$. After blowing-up the base points, we have a pencil $Y \rightarrow \mathbb{P}^1$ with fibre $[Y_t] \in \overline{\mathcal{M}}_d^2$. For this pencil $\lambda_{\mathbb{P}^1} = \chi(\mathcal{O}_Y) + 23 - 1 = 23$ and $\delta_{\mathbb{P}^1} = c_2(Y) + 88 = 91 + b + f$. The condition $\delta_{\mathbb{P}^1}/\lambda_{\mathbb{P}^1} > 13/2$ is satisfied precisely when $d \leq 10$, hence taking into account that such pencils fill up \mathcal{M}_d^2 , we obtain that $\mathcal{M}_{10}^2 \subseteq \Sigma$. Note that $\mathcal{M}_{10}^2 \subseteq \mathcal{M}_8^1$, and as mentioned above, the 8-gonal locus is contained in the intersection of the Brill-Noether divisors.
- In a similar fashion we can prove that $\mathcal{M}_{23,\gamma}(2)$, the locus of curves of genus 23 which are double coverings of curves of genus γ is contained in Σ for $\gamma \leq 5$.

The fact that the slopes of other divisors on $\overline{\mathcal{M}}_{23}$ (or on $\overline{\mathcal{M}}_g$ for arbitrary g) consisting of curves with special geometric characterization, are larger than $6 + 12/(g+1)$, lends further support to the slope hypothesis. In another paper we will compute the class of various divisors on $\overline{\mathcal{M}}_{23}$: the closure in $\overline{\mathcal{M}}_{23}$ of the locus

$$D_e := \{[C] \in \mathcal{M}_{23} : \text{there exists } l \in G_{(23+e)/2}^1(C) \text{ and } p \in C, \text{ such that } w^l(p) \geq e\},$$

for $3 \leq e \leq 19$ and e odd, and the closure of the locus

$$\{[C] \in \mathcal{M}_{23} : C \text{ has a } \mathfrak{g}_{18}^2 \text{ with a 5-fold point, i.e. } \exists D \in C^{(5)} \text{ such that } \mathfrak{g}_{18}^2(-D) = \mathfrak{g}_{13}^1\}.$$

In each case we will show that the slope estimate holds.
